

Forming barium stars through stable RLOF mass transfer from TPAGB-stars

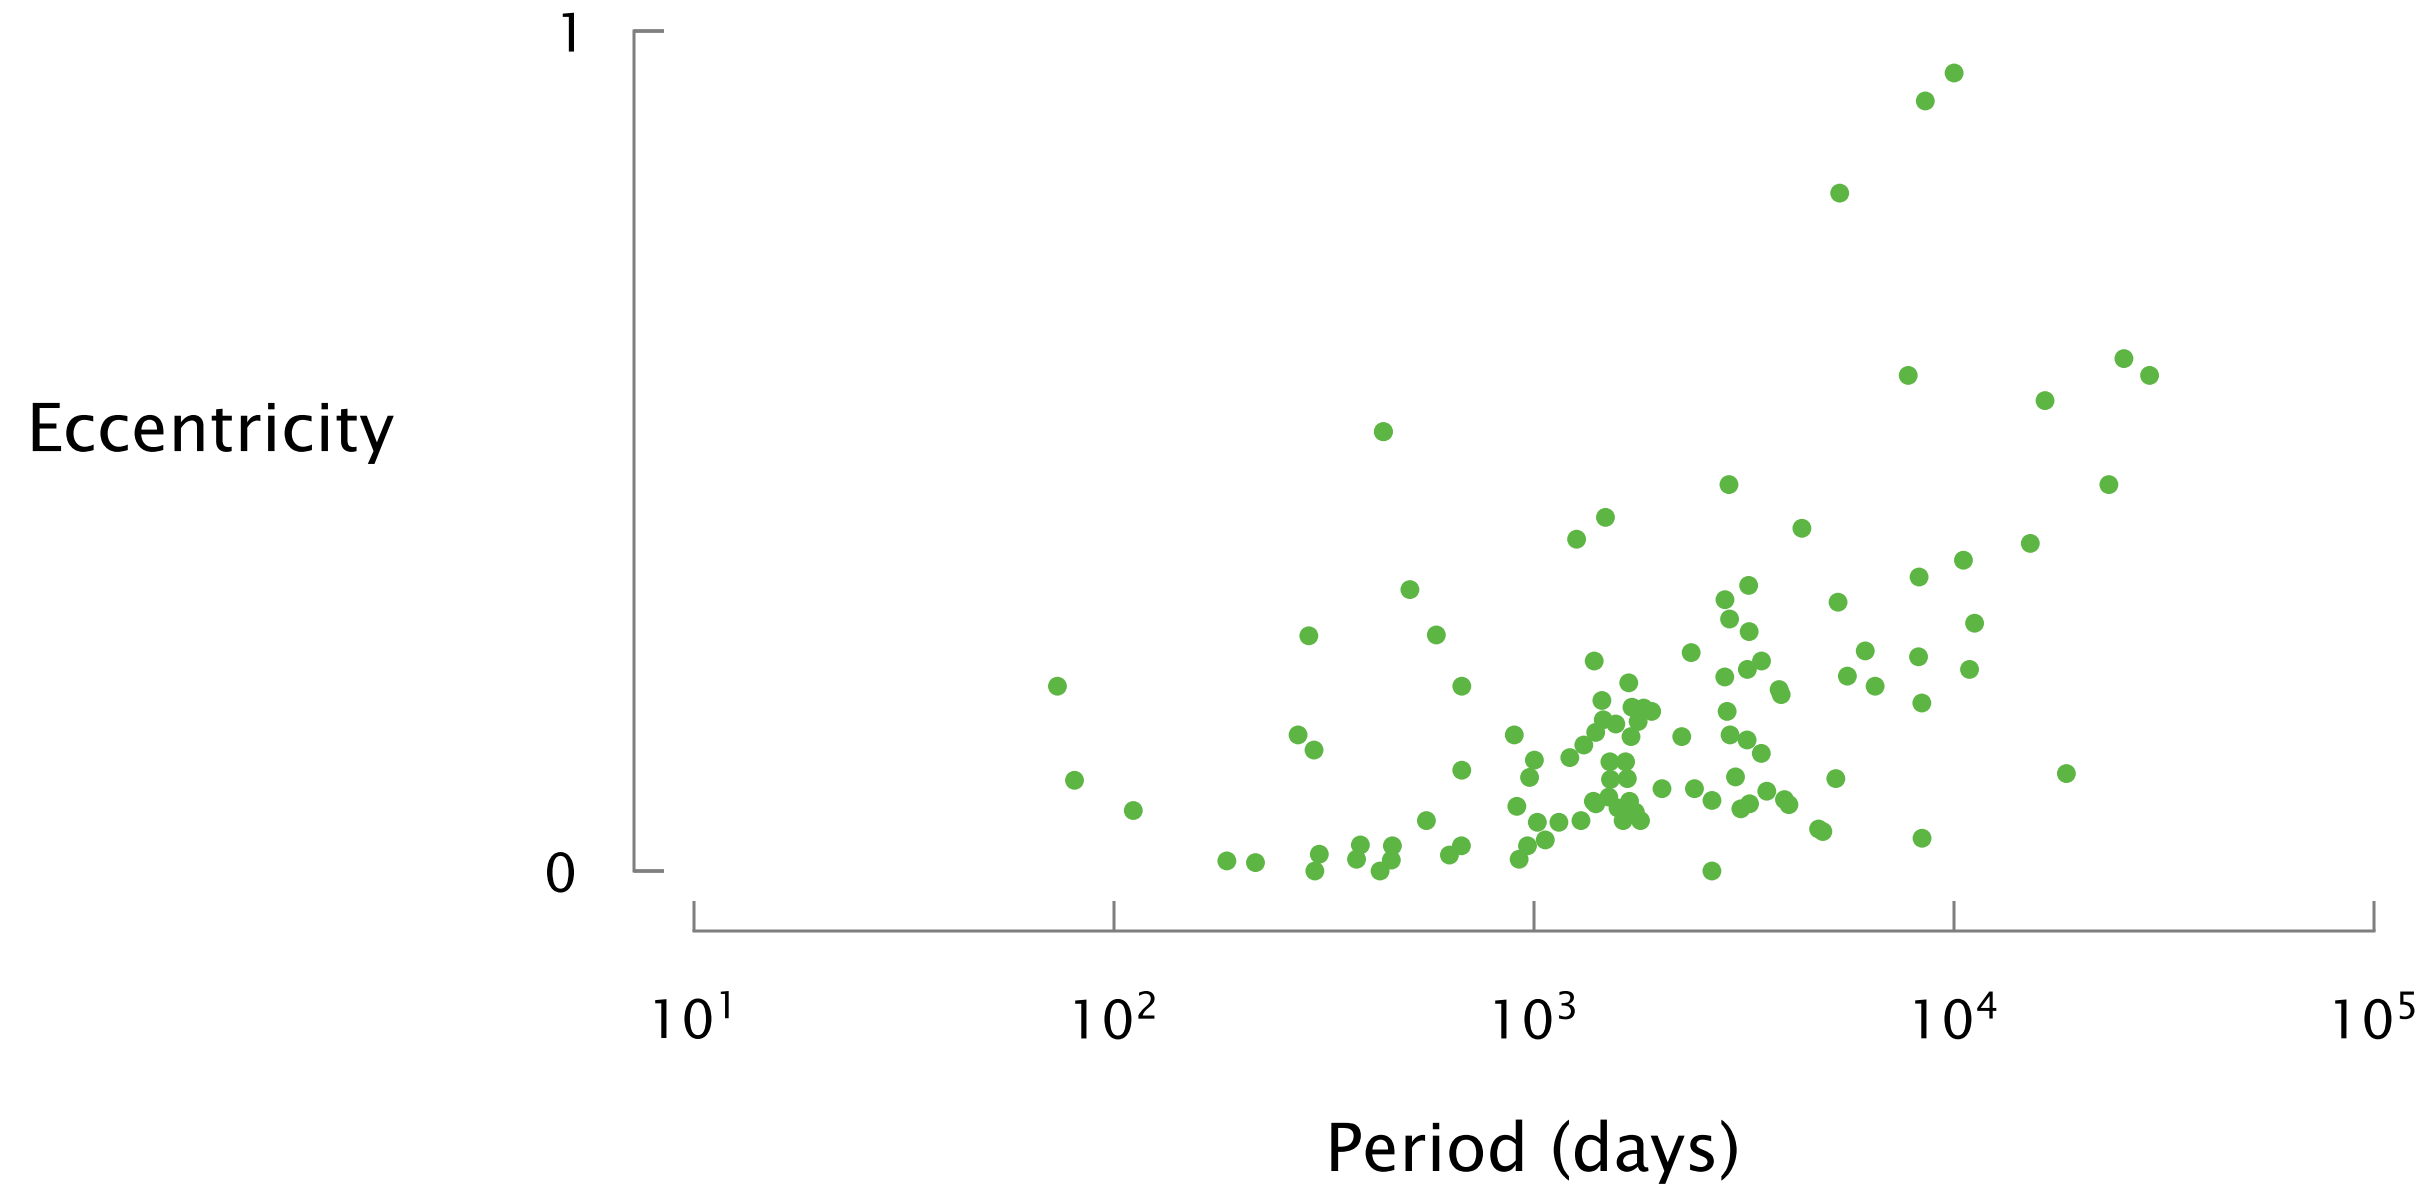

Koen Essers

Post-mass-transfer binaries exist over a broad range of periods

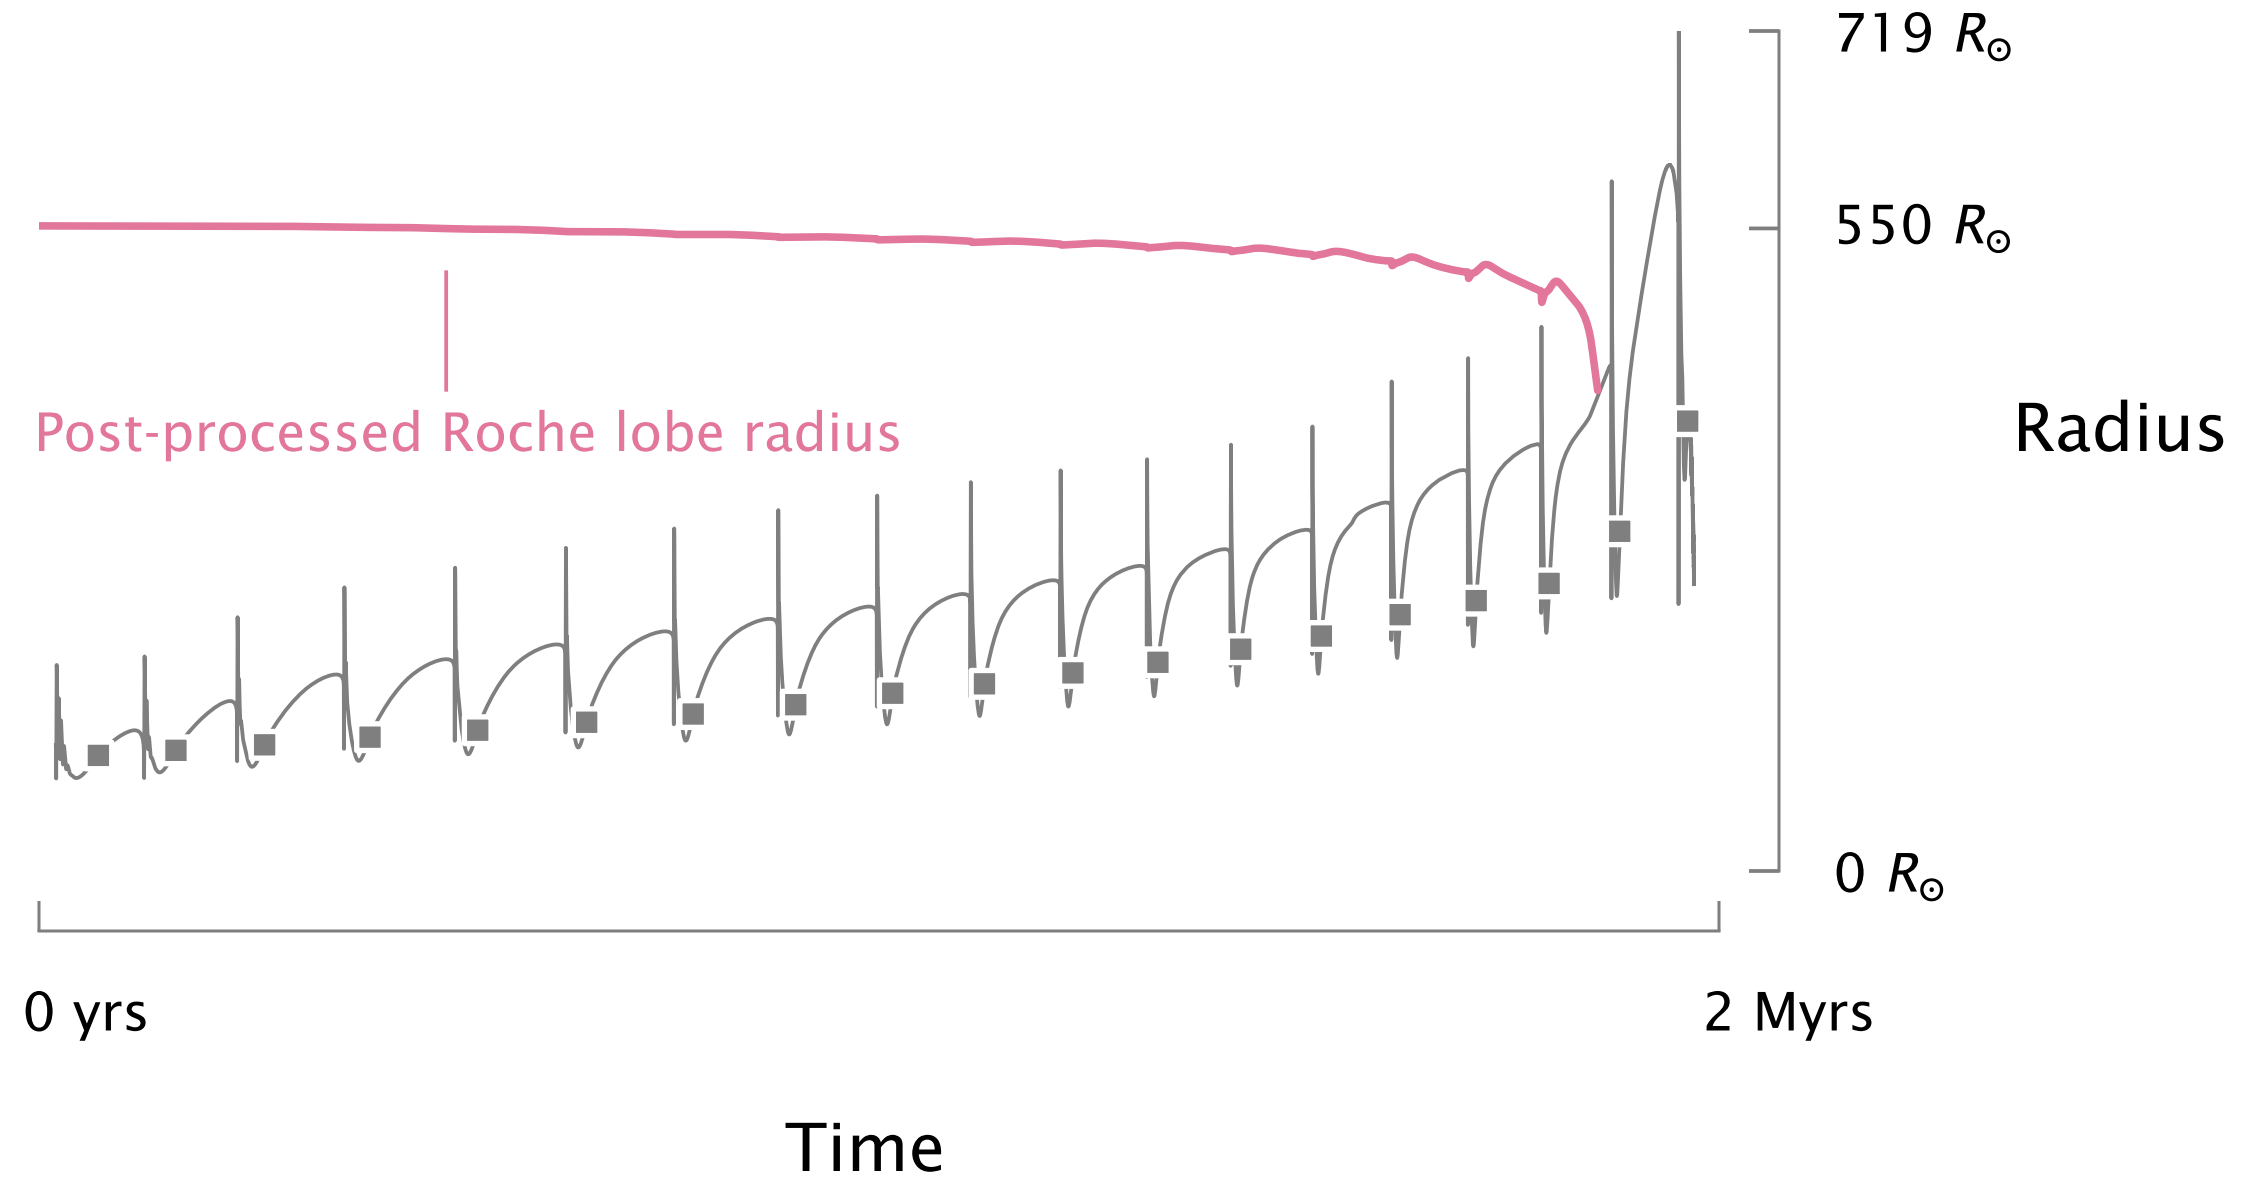

Ba stars have periods incompatible with wind mass transfer or common envelopes

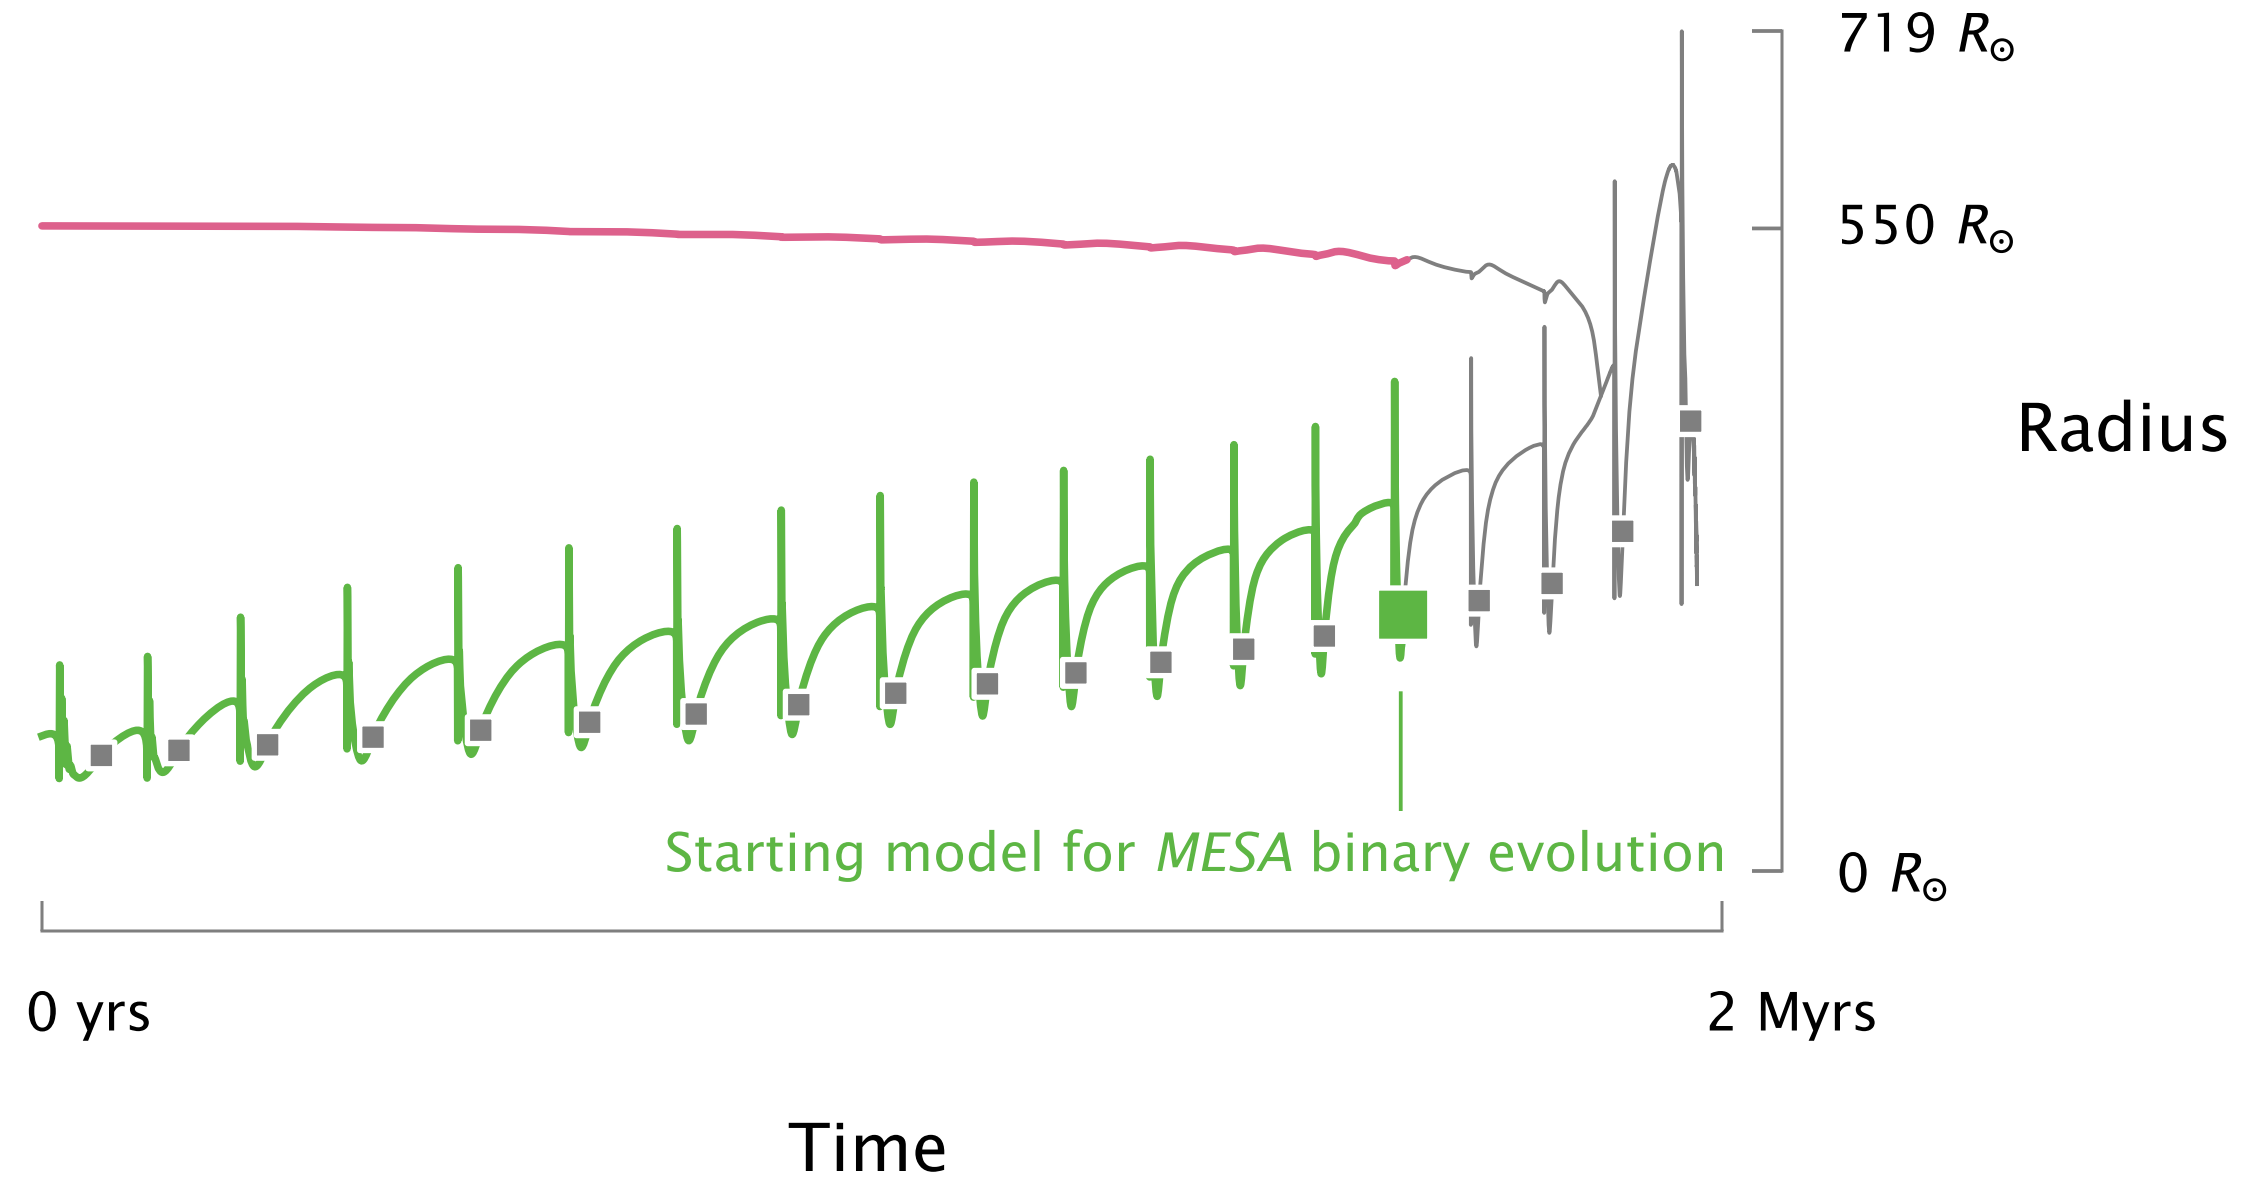

I simulate detailed TP-AGB stars with *MESA*
and I save models to use as binary input

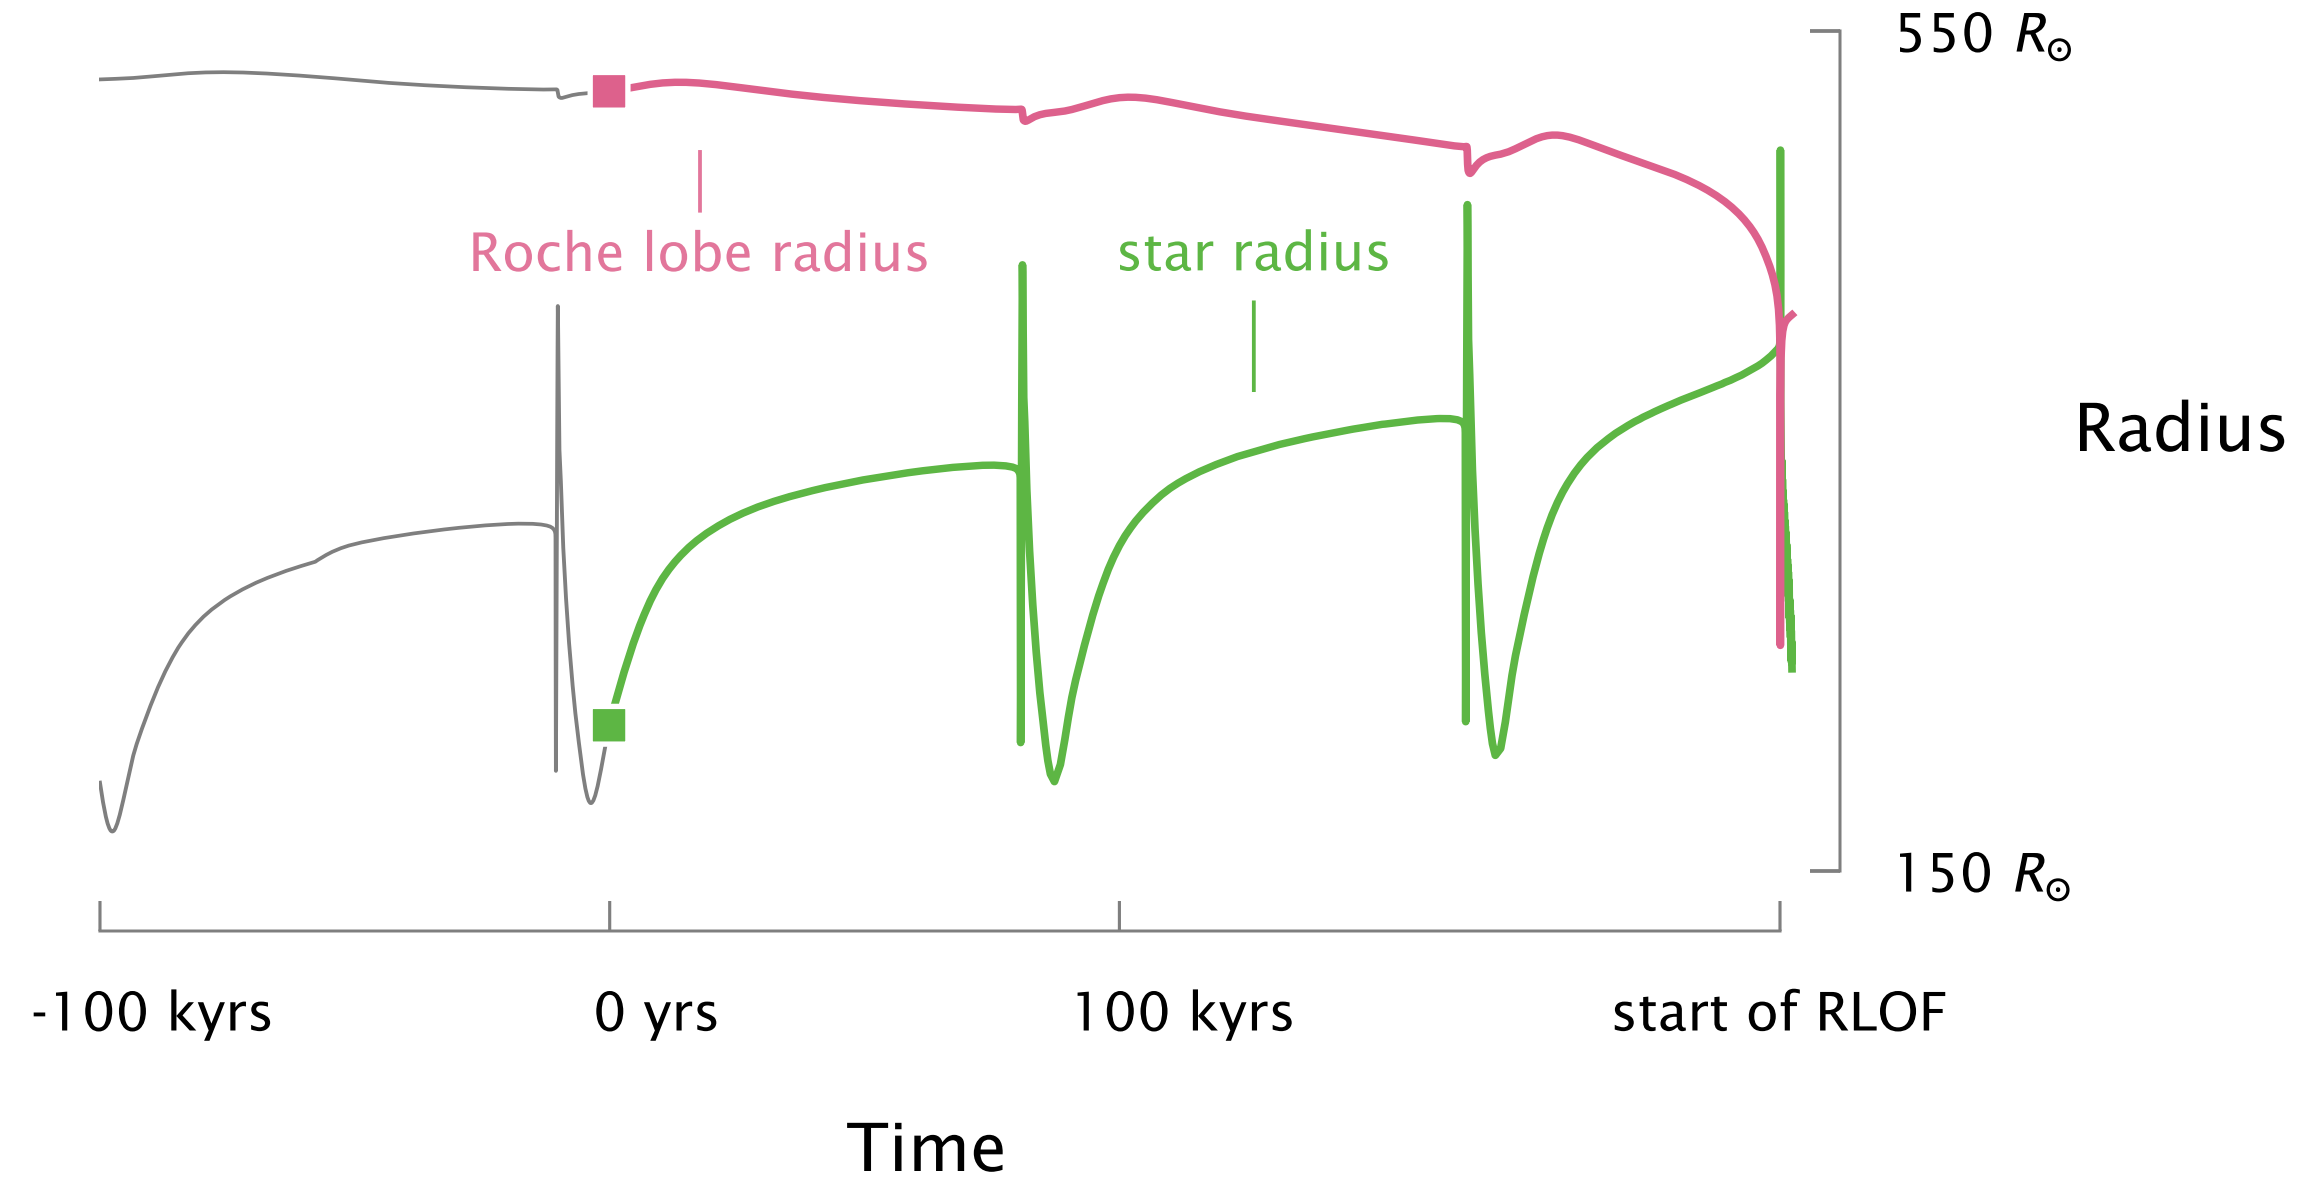

I predict how the binary evolves using single star models and a post-processing step

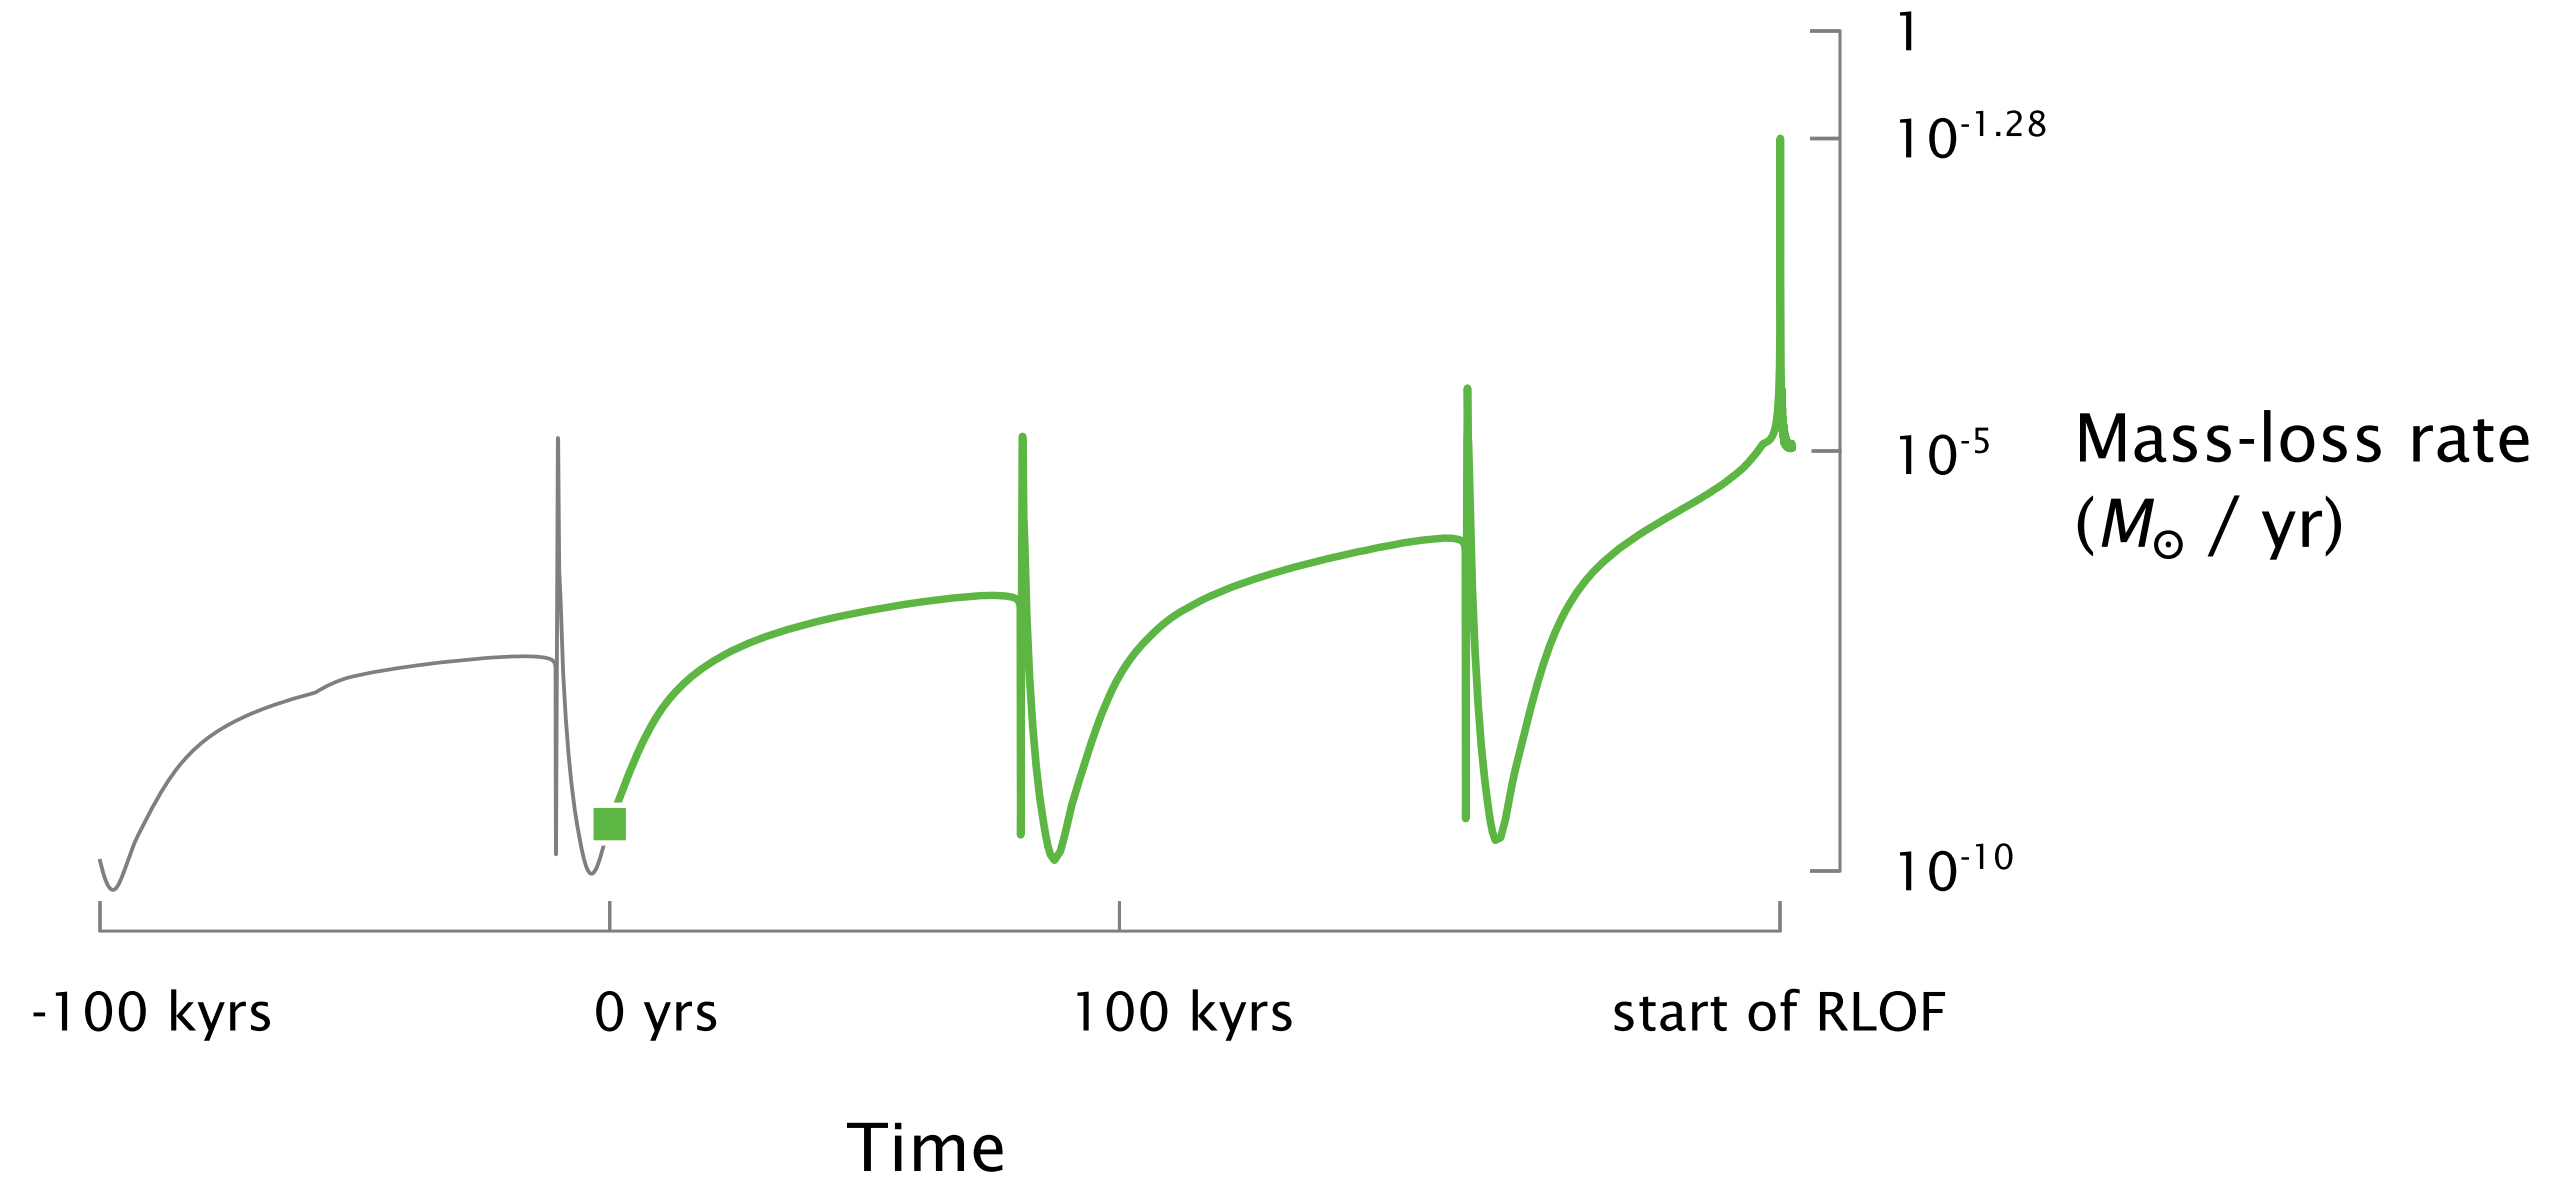

I determine a *MESA* starting model and
infer the rotation, separation and mass-ratio

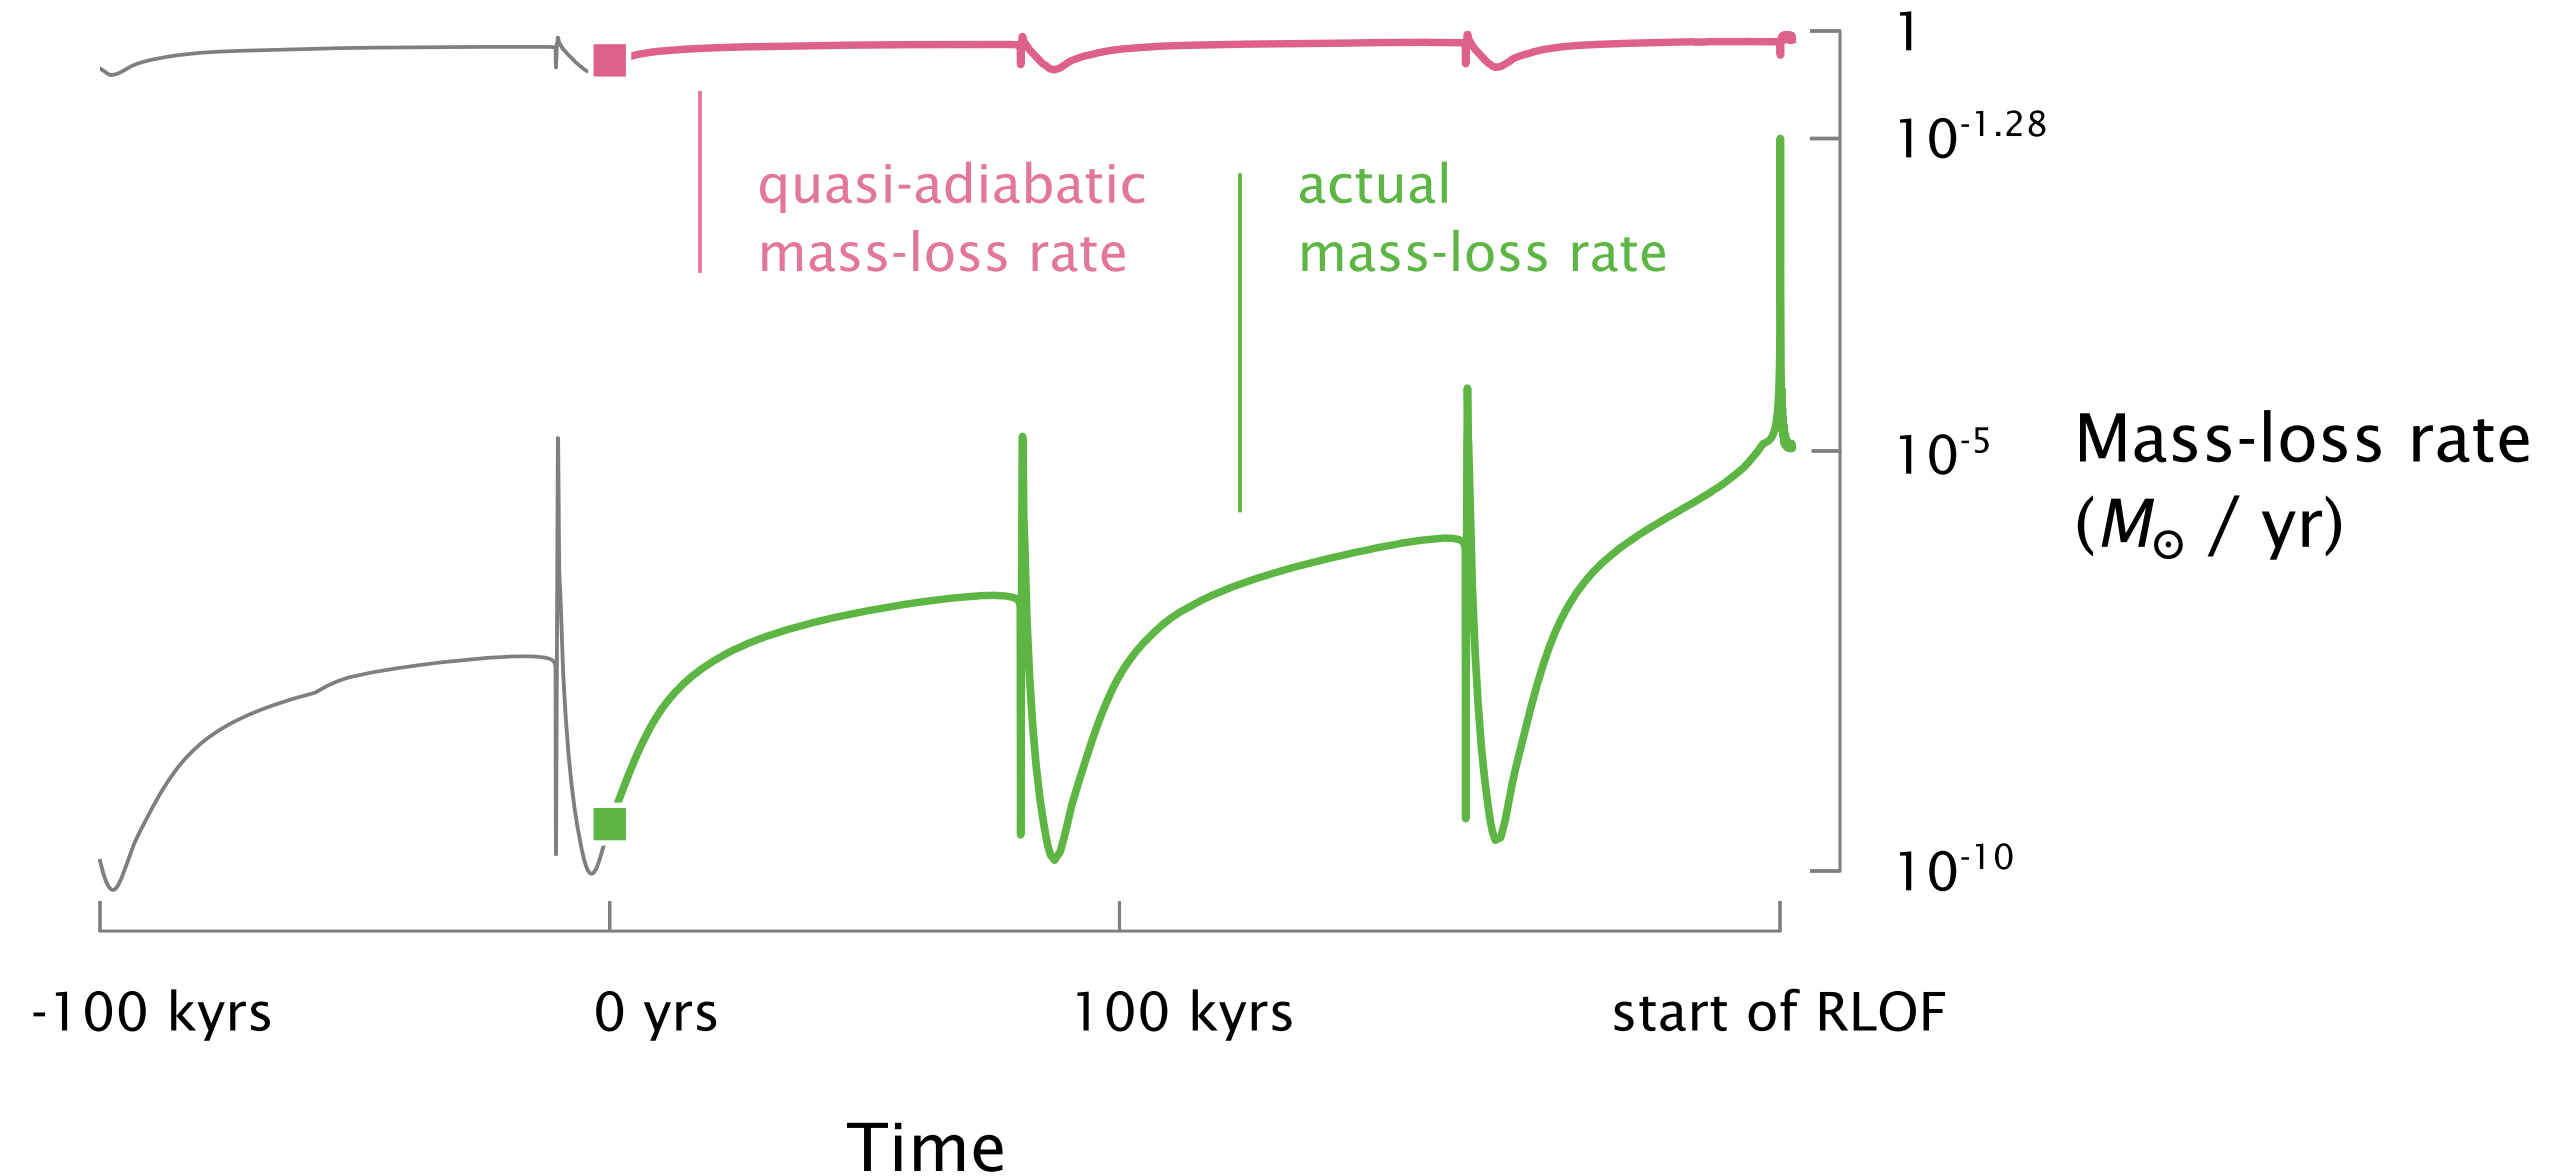

Tides, wind mass-transfer and stellar evolution drive systems into RLOF

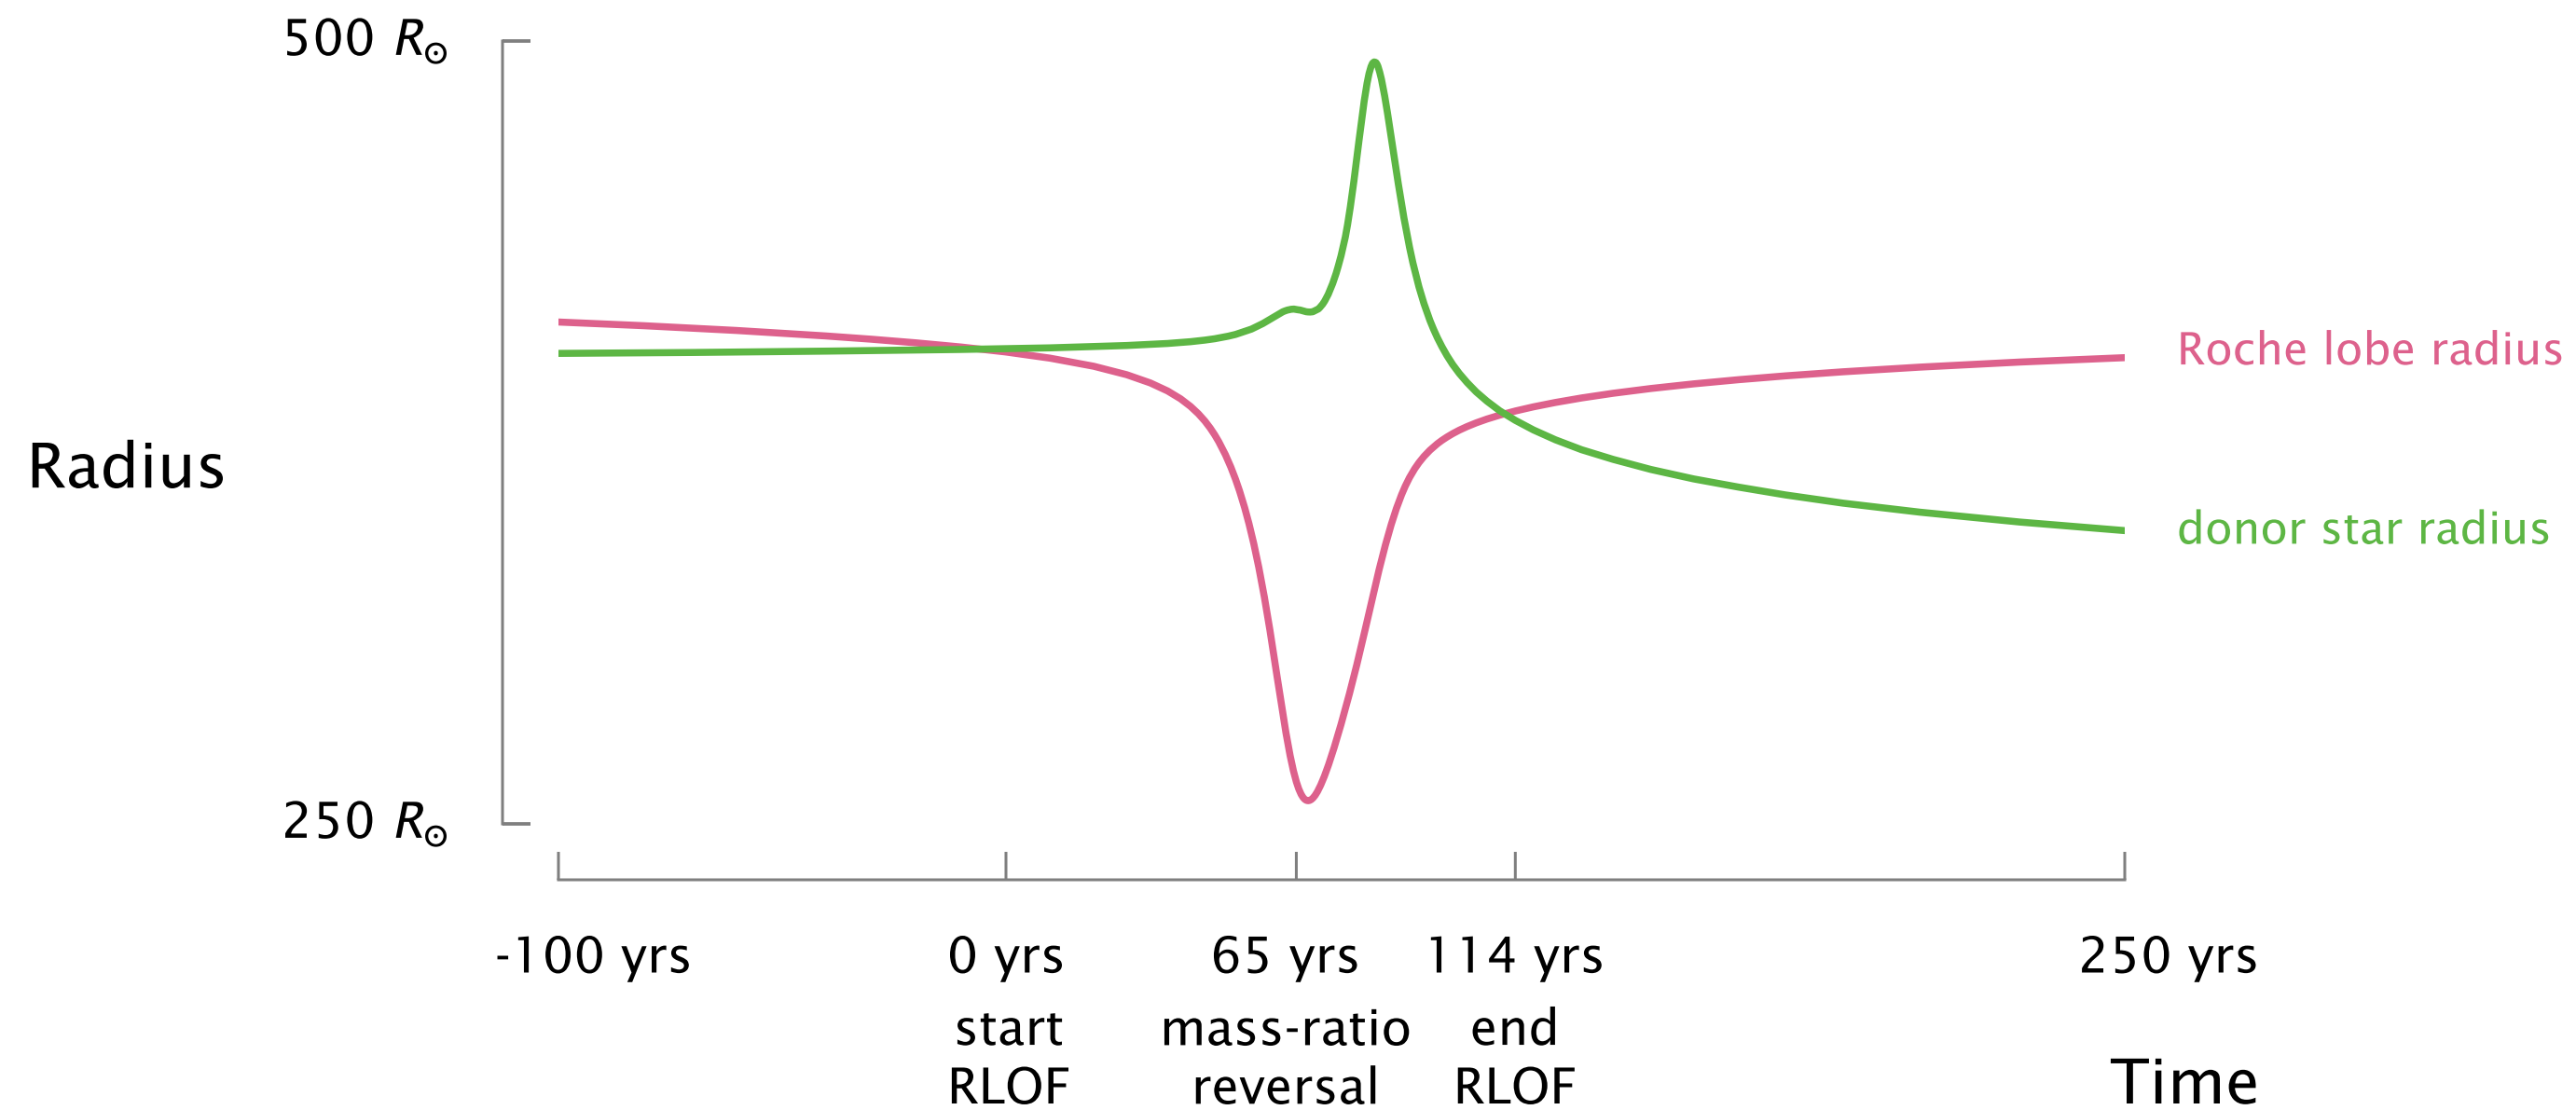

The donor experiences a short but strong burst of mass loss during RLOF

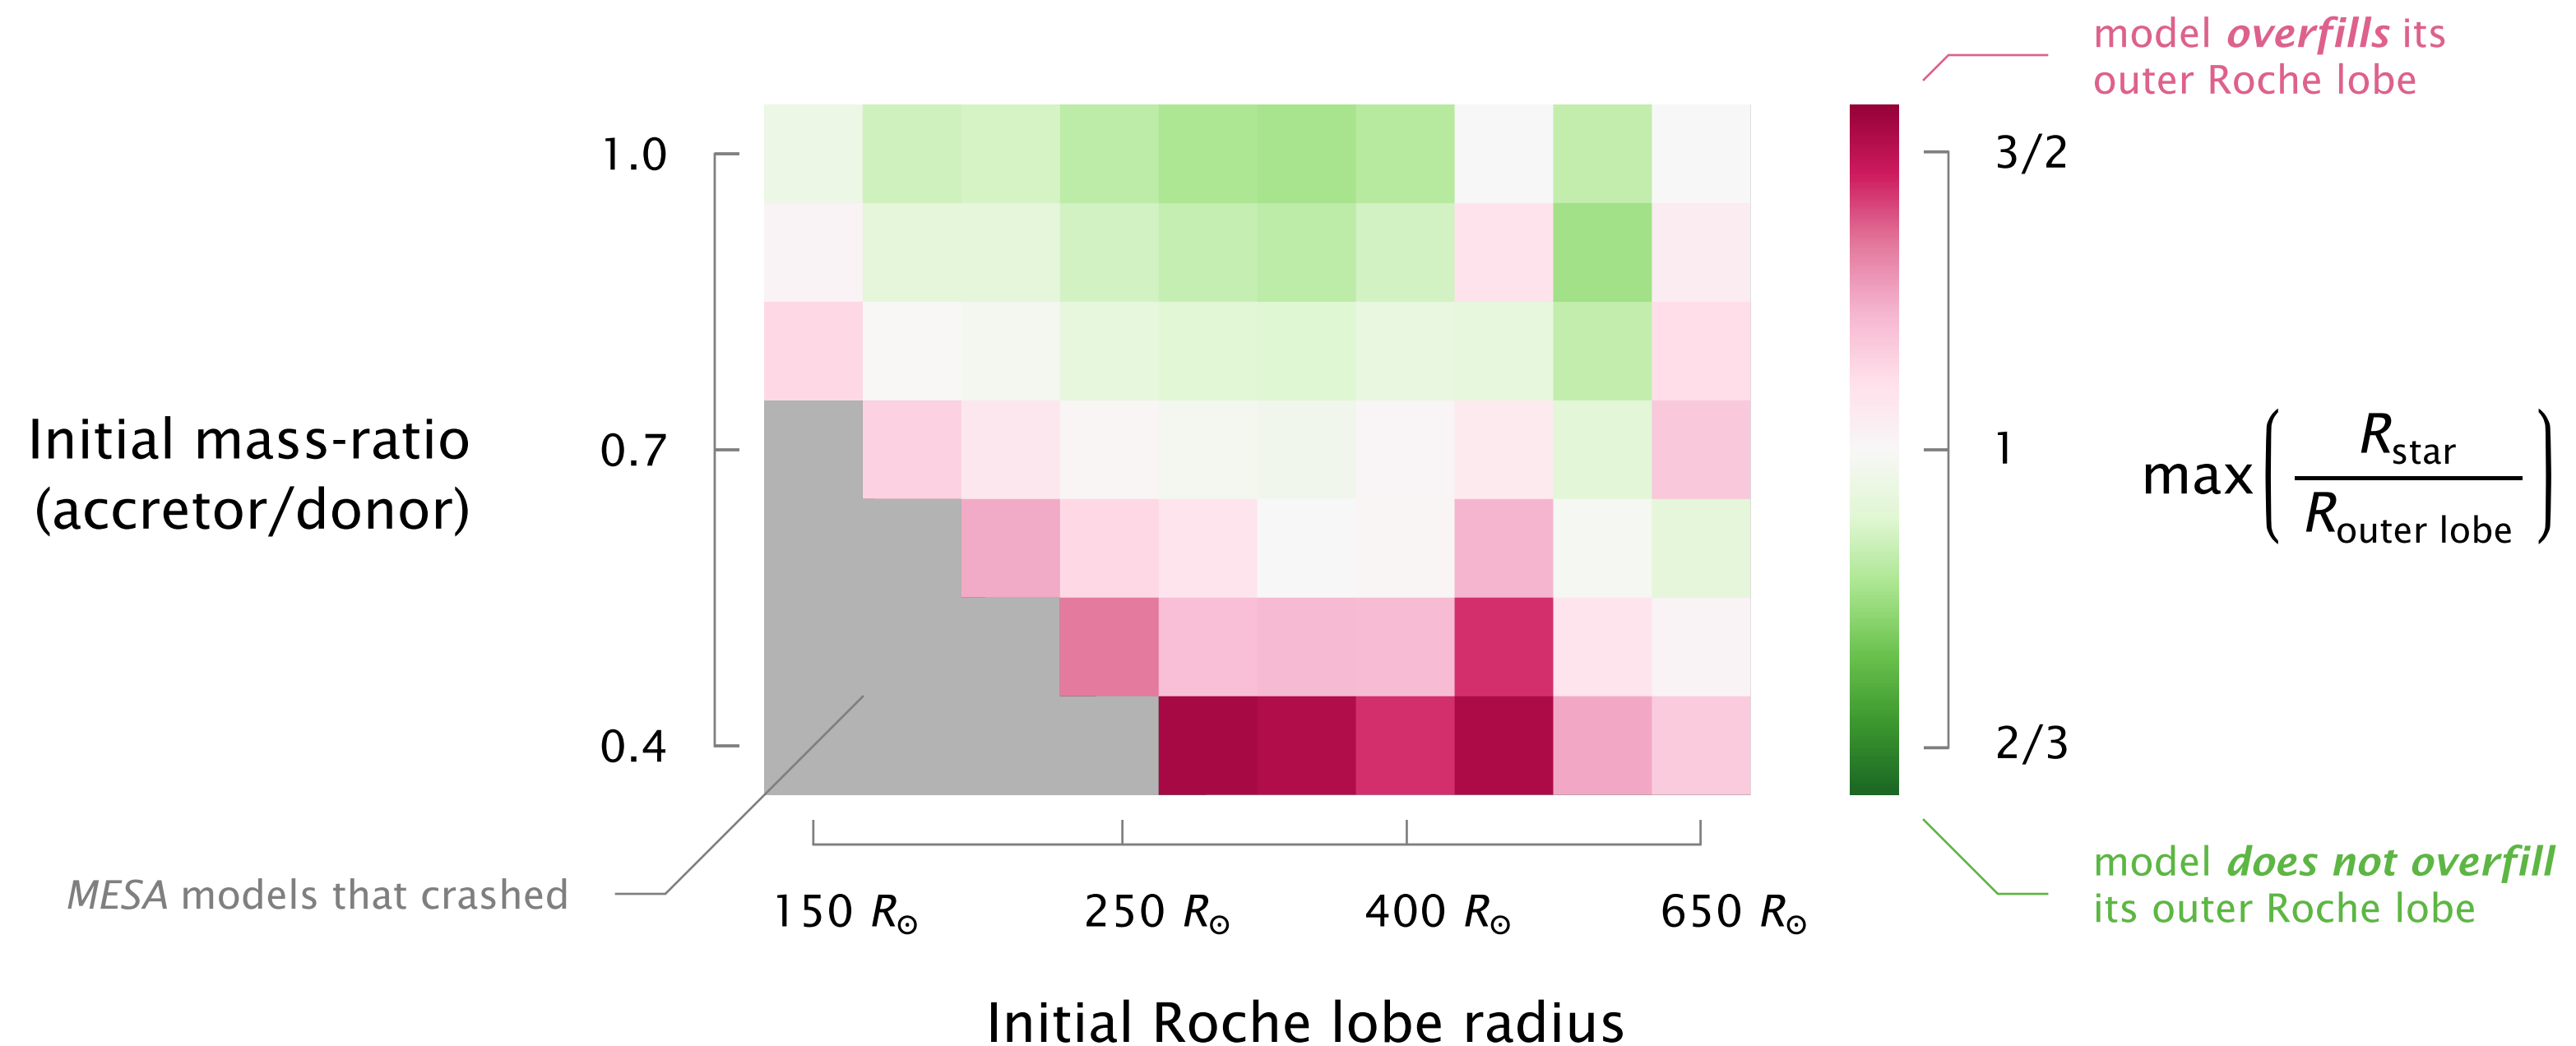

The quasi-adiabatic mass-loss rate is always larger than the actual mass loss rate

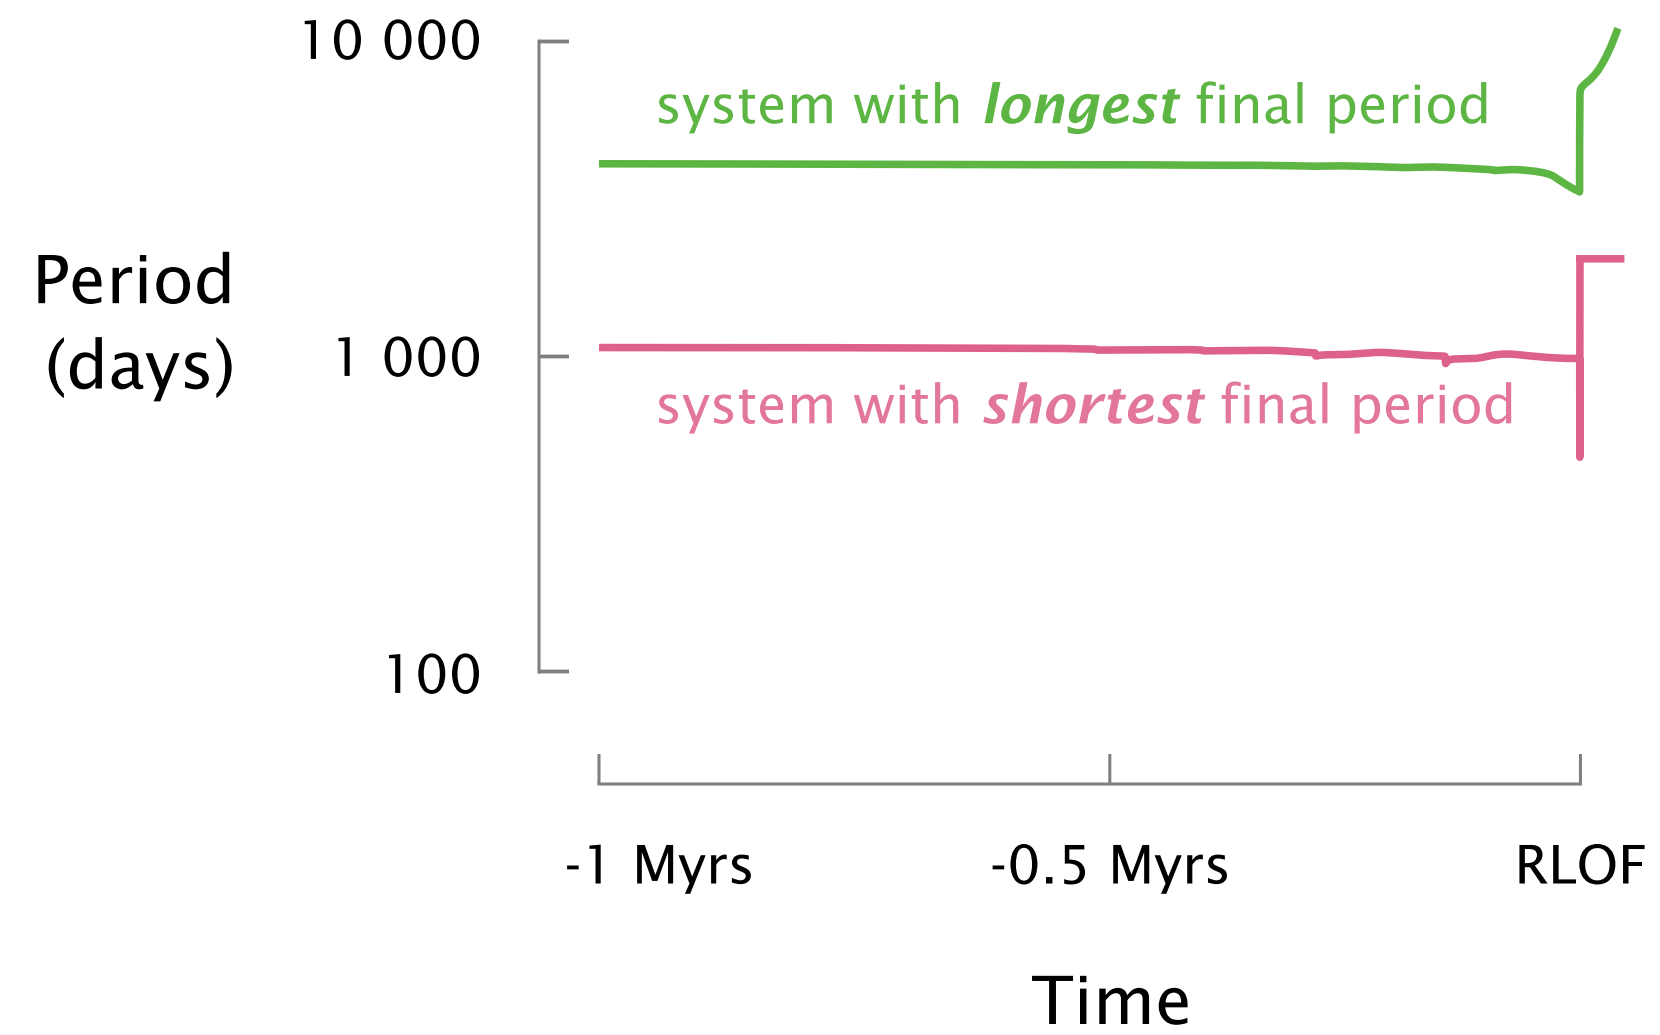

The donor significantly overfills its Roche lobe throughout the short RLOF episode

A significant fraction of models overfill their outer Roche lobe during mass-transfer

Conservative RLOF mass-transfer cannot explain observed systems with short periods
